# Two Way ANOVA

- Two Way Anova is used when there are 2 factors under study.
- Each factor can have 2 or more levels. Example: Gender and Age can be 2 factors.
   Gender with 2 levels as Male and Female
   Age with 3 levels as 18-30,31-50 and >50
- Three hypothesis are tested.

Factor A H0: All group means are equal

H1: At least one mean is different from other means

Factor B H0: All group means are equal

H1: At least one mean is different from other means

Interaction H0: The interaction is not significant

H1: The interaction is significant

# Two Way ANOVA

Total variation is partitioned as below:

**Total SS=** Between Groups SS due to factor A (SSA)

- + Between Groups SS due to factor B (SSB)
- + Interaction SS due to factor A and B (SSAB)
- + Error SS (SSE)

where, SS stands for sum of squares

# Case Study

We will illustrate Two Way Anova in Python using following case study

### **Background**

A large company is assessing the difference in 'Satisfaction Index' of employees in Finance, Marketing and Client-Servicing departments. Experience level is also considered in the study.( <=5 years and >5 years)

### **Objective**

To test the equality of the satisfaction index among employees of three departments (CS, Marketing, Finance) and among different experience bands.

### **Sample Size**

Sample size: 36

Variables: satindex, dept, exp

# Data Snapshot

Two Way Anova

		Variables	
	satindex	dept	exp
	75	FINANCE	lt5
	56	FINANCE	lt5
	62	FINANCE	gt5
า	66	FINANCE	gt5
	58	FINANCE	gt5
2	58	MARKETIN	lt5
,	63	MARKETIN	lt5
$\prec$	53	MARKETIN	lt5
;	74	MARKETIN	lt5
<b>5</b>	77	MARKETIN	lt5
2	69	MARKETIN	lt5
)	57	MARKETIN	gt5
	70	MARKETIN	gt5
	68	MARKETIN	gt5
	77	CS	lt5

Columns	Description	Type	Measurement	Possible values
Satindex	Satisfaction Index	Numeric	-	Positive Values
Dept	Department	Character	MARKETING, CS, FINANCE	3
Ехр	Years of Experience (grouped)	Character	lt5 = less than 5, gt5 = greater than 5	2

# Two Way ANOVA

Testing equality of means in two factors.

**Objective** 

To compare employee satisfaction index in three departments (CS,

Marketing, Finance) and two experience level based groups.

### Null Hypothesis

 $(H_{01})$ : Average satisfaction index is equal for 3 departments.

 $(H_{02})$ : Average satisfaction index is equal for 2 experience levels.

 $(H_{03})$  Interaction effect(dept\*exp) is not significant on satisfaction index.

The test statistic is computed for each of these null hypothesis.

Reject the null hypothesis if p-value < 0.05

# Two Way ANOVA in Python

```
# Import data
import pandas as pd
data = pd.read_csv('Two Way Anova.csv')

# ANOVA Table
import statsmodels.api as sm
from statsmodels.formula.api import ols

model = ols('satindex ~ C(dept) + C(exp) + C(dept) : C(exp)',
data=data).fit()
sm.stats.anova_lm(model, typ=2)
```

- 'sm.stats.anova\_lm' is the Python function for ANOVA.
- formula specifies 'satindex' as analysis
   (dependent) variable and 'dept' and 'exp' as factor
   (independent) variables.
- □ C(dept) : C(exp) specifies the interaction effect.

# Two Way ANOVA in Python

#### # Output:

```
PR(>F)
                     sum sq
C(dept)
                164,222222
                                  1.678973
                                             0.203624
C(exp)
                 78.027778
                                  1.595479
                                            0.216274
C(dept):C(exp)
                 20.222222
                                  0.206748 0.814374
Residual
                1467, 166667 30.0
                                        NaN
                                                  NaN
```

### Interpretation:

- Since p-value is >0.05 for all three (dept, exp and dept\*exp ), do not reject H0 for all three tests.
   There is no significant difference in satisfaction index among 3 different departments and 2 experience levels.
- Also interaction effect is not significant.

# Knowledge check question

- A large retailer is testing a marketing campaign on 24 stores. 8 stores are selected randomly from each of 3 zones.
- The variable of interest is 'sales increment(%) during campaign month'. Objective is to test whether the campaign is equally effective in 3 regions. Data is given below.

NORTH	WEST	SOUTH
8	10.2	5.3
12.5	9.3	5.8
9.2	9.9	6
6.7	8.7	7.1
9.4	9.1	7
5.9	10.2	6.1
7.7	9.5	6.3
6.9	10	7.3

Is this One-way ANOVA problem or Two-way ANOVA problem?

**ANSWER:** One-way ANOVA

**EXPLANATION**: There is only one factor (zone) with 3 levels (North, West, South).

# Quick Recap

Two Way Anova

• The two way anova is extension of one way anova when we have 2 factors in the study instead of one.

Null Hypothesis
Drawing Inference

- Equality of means for levels in factor A
- Equality of means for levels in factor B
- No Interaction effect between 2 factors
- Total sum of squares is split into 4 parts and each hypothesis is tested.
